Reason for testing Test performed

Gamete donor Invitae Carrier Screen

RESULT: POSITIVE

This carrier test evaluated 514 gene(s) for genetic changes (variants) that are associated with an increased risk of having a child with a genetic condition. Knowledge of carrier status for one of these conditions may provide information that can be used to assist with family planning and/or preparation. Carrier screening is not intended for diagnostic purposes. To identify a potential genetic basis for a condition in the individual being tested, diagnostic testing for the gene(s) of interest is recommended.

This test shows the presence of clinically significant genetic change(s) in this individual in the gene(s) indicated below. No other clinically significant changes were identified in the remaining genes evaluated with this test.

| RESULTS | GENE | VARIANT(S) | INHERITANCE | PARTNER TESTING RECOMMENDED |
|---|-------|------------------------------------|---------------------|--------------------------------|
| Carrier: CFTR-related conditions | CFTR | c.1521_1523del (p.Phe508del) | Autosomal recessive | Yes |
| Carrier: Combined malonic and methylmalonic aciduria | ACSF3 | c.1075G>A (p.Glu359Lys) | Autosomal recessive | Yes |
| Carrier: Fructose-1,6-bisphosphatase deficiency | FBP1 | Deletion (Exon 1) | Autosomal recessive | Yes |
| Carrier: Muscular dystrophy-dystroglycanopathy (POMT1-related) | POMT1 | c.579_580del (p.Val195Argfs*42) | Autosomal recessive | Yes |
| Carrier: Oculocutaneous albinism types 1A and 1B | TYR | c.325G>A (p.Gly109Arg) | Autosomal recessive | Yes |

Next steps

- See the table above for recommendations regarding testing of this individual's reproductive partner.
- Even for genes that have a negative test result, there is always a small risk that an individual could still be a carrier. This is called "residual risk." See the Carrier detection rates and residual risks document.
- Discussion with a physician and/or genetic counselor is recommended to further review the implications of this test result and to understand these results in the context of any family history of a genetic condition.
- All patients, regardless of result, may wish to consider additional screening for hemoglobinopathies by complete blood count (CBC) and hemoglobin electrophoresis, if this has not already been completed.
- Individuals can register their tests at https://www.invitae.com/patients/ to access online results, educational resources, and next steps.

Invitae #: RQ5318945

Clinical summary

RESULT: CARRIER

CFTR-related conditions

A single Pathogenic variant, c.1521_1523del (p.Phe508del), was identified in CFTR.

What are CFTR-related conditions?

CFTR-related conditions encompass a spectrum of disorders that typically impact the respiratory and/or digestive systems, and cause male infertility. Cystic fibrosis (CF) is typically a childhood-onset disease in which abnormally thick mucus production can cause a variety of symptoms including recurrent respiratory infections and progressive lung disease, as well as nutritional deficiencies and poor growth due to deficiency of enzymes produced by the pancreas to digest food (pancreatic insufficiency). Symptoms range from mild to severe. Prognosis depends on the severity of symptoms as well as response to treatments; many affected individuals live well into adulthood. Milder forms of CFTR-related conditions include congenital absence of the vas deferens (CAVD) associated with male infertility, variable respiratory manifestations, and hereditary pancreatitis. Life span is not typically impacted with less severe CFTR-related conditions. Intellect is not affected with the various CFTR-related conditions. The combination of variants identified in an affected individual impacts the observed clinical features and severity of the symptoms. Additional genetic and environmental factors are believed to play a role in determining the risk of developing these complex CFTR-related conditions.

Additionally, individuals with a single disease-causing CFTR variant (heterozygous carriers) may have an approximately 4-10 fold increased risk for chronic pancreatitis, although the absolute risk of pancreatitis remains low (less than 1 in 100). Hereditary pancreatitis is characterized by recurrent episodes of acute inflammation of the pancreas (pancreatitis) beginning in childhood or adolescence, leading to chronic pancreatitis. Chronic pancreatitis is a risk factor for pancreatic cancer. Due to this potential increased risk for chronic pancreatitis, heterozygous carriers may consider follow-up with a medical provider.

Follow-up depends on each affected individual's specific situation, and discussion with a healthcare provider should be considered.

Next steps

Carrier testing for the reproductive partner is recommended.

(+) If your partner tests positive:

In autosomal recessive inheritance, an individual must have disease-causing genetic changes in each copy of the CFTR gene to be affected. Carriers, who have a diseasecausing genetic change in only one copy of the gene, typically do not have symptoms. When both reproductive partners are carriers of an autosomal recessive condition, there is a 25% chance for each child to have the condition.

If your partner tests negative:

A negative carrier test result reduces, but does not eliminate, the chance that a person may be a carrier. The risk that a person could still be a carrier, even after a negative test result, is called a residual risk. See the table below for your partner's hypothetical

Autosomal recessive inheritance 25% 50% 25%

residual risk after testing negative for CFTR-related conditions. These values are provided only as a guide, are based on the detection rate for the condition as tested at Invitae, and assume a negative family history, the absence of symptoms, and vary based on the ethnic background of an individual. For genes associated with both dominant and recessive inheritance, the numbers provided apply to the recessive condition(s) associated with the gene.

Combined malonic and methylmalonic aciduria

A single Pathogenic variant, c.1075G>A (p.Glu359Lys), was identified in ACSF3.

What is combined malonic and methylmalonic aciduria?

Combined malonic and methylmalonic aciduria (CMAMMA) is a condition that causes increased levels of malonic acid and methylmalonic acid in the blood and urine. A large majority of affected individuals do not have any signs or symptoms of the condition (asymptomatic). However, a number of individuals have been reported with a wide variety of symptoms including but not limited to early onset developmental delay and/or seizures, or adult onset memory decline. Current evidence is insufficient to determine whether or not the symptoms reported in these individuals were caused by CMAMMA.

Proposed management of CMAMMA may include a diet high in carbohydrates and low in protein. Follow-up depends on each affected individual's specific situation, and discussion with a healthcare provider should be considered.

Next steps

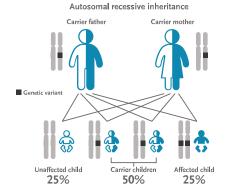

Carrier testing for the reproductive partner is recommended.

If your partner tests positive:

In autosomal recessive inheritance, an individual must have disease-causing genetic changes in each copy of the ACSF3 gene to be affected. Carriers, who have a diseasecausing genetic change in only one copy of the gene, typically do not have symptoms. When both reproductive partners are carriers of an autosomal recessive condition, there is a 25% chance for each child to have the condition.

If your partner tests negative:

Fructose-1,6-bisphosphatase deficiency

A single Pathogenic variant, Deletion (Exon 1), was identified in FBP1.

What is fructose-1,6-bisphosphatase deficiency?

Fructose-1,6-bisphosphatase deficiency is a condition in which individuals have difficulty with the production of a sugar called glucose. Symptoms typically present before 4 months of age or in early childhood, and include potentially life-threatening episodes of low blood sugar (hypoglycemia), a buildup of lactic acid in the body (lactic acidosis), the use of fat, rather than glucose, as fuel for the body (ketosis), breathing abnormalities, seizures, and coma. Other symptoms may include low muscle tone (hypotonia), an enlarged liver (hepatomegaly), a rapid heart rate (tachycardia), and sleepiness. Episodes are often triggered by prolonged fasting, fever, vomiting, diarrhea, infections, or ingestion of large amounts of a sugar called fructose. Between episodes, individuals usually do not have any signs or symptoms of the condition (asymptomatic). Untreated individuals may experience organ failure. Blindness and a severe and potentially life-threatening bodily response to infection (sepsis) have also been reported. Although most affected children have normal growth and development, some have intellectual disability. Fructose-1,6-bisphosphatase deficiency is readily treatable, and early treatment, including fasting precautions and adherence to a specific diet, may prevent or reduce severity of symptoms. Follow-up depends on each affected individual's specific situation, and discussion with a healthcare provider should be considered.

Invitae #: RQ5318945

Muscular dystrophy-dystroglycanopathy (POMT1-related)

A single Pathogenic variant, c.579_580del (p.Val195Argfs*42), was identified in POMT1.

What is muscular dystrophy-dystroglycanopathy (POMT1-related)?

Muscular dystrophy-dystroglycanopathies (ADGs) refer to a spectrum of conditions that affect the muscles, eyes, and brain. There are three subtypes which are typically used to refer to varying levels of symptom severity: Type A (most severe, also referred to as Walker-Warburg syndrome and muscleeye-brain disease), Type B (intermediate severity), and type C (least severe, also referred to as limb-girdle muscular dystrophy). ADGs can be caused by changes in several different genes. While the clinical severity in individuals with ADGs is highly variable, common features in all affected individuals include muscle weakness with loss of muscle mass (muscular dystrophy) predominantly in the arm and leg muscles that are closest to the body (proximal muscles), and elevated serum creatine kinase levels. ADGs typically present in infancy or childhood, though onset in adulthood has been reported in individuals with type C. Clinical features of type A include characteristic brain and eye abnormalities, severe intellectual disability, and low muscle tone (hypotonia). Individuals with type A dystroglycanopathy may die in infancy or childhood. The symptoms of type B are typically less severe than type A and may not include brain and eye abnormalities. Type C is the most mild subtype and is characterized by later onset of proximal muscular weakness (limb-girdle muscular dystrophy), typically without other features. Individuals with type B or C ADG may live to adulthood, though they may never walk or they may become wheelchair-bound later in life. Other variable features of ADGs include weakened heart muscle (cardiomyopathy), developmental delay, and breathing problems. Certain genetic forms of ADG may be associated with specific muscle biopsy findings. Follow-up depends on each affected individual's specific situation, and discussion with a healthcare provider should be considered.

Next steps

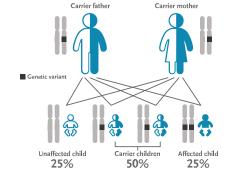

Carrier testing for the reproductive partner is recommended.

(+) If your partner tests positive:

In autosomal recessive inheritance, an individual must have disease-causing genetic changes in each copy of the POMT1 gene to be affected. Carriers, who have a diseasecausing genetic change in only one copy of the gene, typically do not have symptoms. When both reproductive partners are carriers of an autosomal recessive condition, there is a 25% chance for each child to have the condition.

If your partner tests negative:

A negative carrier test result reduces, but does not eliminate, the chance that a person may be a carrier. The risk that a person could still be a carrier, even after a negative test result, is called a residual risk. See the table below for your partner's hypothetical

Oculocutaneous albinism types 1A and 1B

A single Pathogenic variant, c.325G>A (p.Gly109Arg), was identified in TYR.

What are oculocutaneous albinism types 1A and 1B?

Oculocutaneous albinism (OCA) is a condition that causes decreased color (hypopigmentation) of the hair, skin, and eyes. Affected individuals produce a reduced amount of melanin, the pigment that gives skin, hair, and eyes their color, resulting in hypopigmentation. Additional symptoms of OCA include reduced visual acuity (farsightedness or nearsightedness), increased sensitivity to light (photophobia), involuntary eye movements (nystagmus), and eyes that do not look in the same direction (strabismus). Other eye findings, such as reduced pigmentation of the light-sensitive tissue that lines the back of the eye (retina) and misrouting of the nerves of the eye (optic nerves), are seen on ophthalmologic exam. Individuals with fair complexions have an increased risk for skin cancers. Intelligence is not typically affected. Individuals with oculocutaneous albinism type 1 (OCA1) are often diagnosed during the first year of life based on hypopigmentation, reduced visual acuity, nystagmus, photophobia, and other eye findings. Vision typically stabilizes after childhood. OCA1 has two sub-types. Individuals with OCA1A have no melanin production in any tissue, and the condition is characterized by white skin and hair, and irises which are blue and fully translucent. Individuals with OCA1B have minimal melanin production, and have white skin, white or light yellow hair, and blue irises. Treatment is aimed at correcting vision and providing visual aids, or other visual resources. Sun protection is essential due to the increased risk for skin cancer.

Next steps

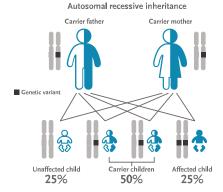

Carrier testing for the reproductive partner is recommended.

+ If your partner tests positive:

In autosomal recessive inheritance, an individual must have disease-causing genetic changes in each copy of the TYR gene to be affected. Carriers, who have a disease-causing genetic change in only one copy of the gene, typically do not have symptoms. When both reproductive partners are carriers of an autosomal recessive condition, there is a 25% chance for each child to have the condition.

If your partner tests negative:

Results to note

SMN1

Negative result. SMN1: 2 copies; c.*3+80T>G not detected.

Pseudodeficiency allele(s)

- Benign change, c.1685T>C (p.lle562Thr), known to be a pseudodeficiency allele, identified in the GALC gene. Pseudodeficiency alleles are not known to be associated with disease, including Krabbe disease.
- The presence of a pseudodeficiency allele does not impact this individual's risk to be a carrier. Individuals with pseudodeficiency alleles may exhibit false positive results on related biochemical tests, including newborn screening. However, pseudodeficiency alleles are not known to cause disease, even when there are two copies of the variant (homozygous) or when in combination with another disease-causing variant (compound heterozygous). Carrier testing for the reproductive partner is not indicated based on this result.

Variant details

ACSF3, Exon 6, c.1075G>A (p.Glu359Lys), heterozygous, PATHOGENIC

- This sequence change replaces glutamic acid, which is acidic and polar, with lysine, which is basic and polar, at codon 359 of the ACSF3 protein (p.Glu359Lys).
- This variant is present in population databases (rs150487794, gnomAD 0.1%), and has an allele count higher than expected for a pathogenic variant.
- This missense change has been observed in individual(s) with combined malonic and methylmalonic aciduria (PMID: 21785126, 21841779, 26915364, 30740739; Invitae). In at least one individual the data is consistent with being in trans (on the opposite chromosome) from a pathogenic variant. It has also been observed to segregate with disease in related individuals.
- ClinVar contains an entry for this variant (Variation ID: 31136).
- Advanced modeling of protein sequence and biophysical properties (such as structural, functional, and spatial information, amino acid conservation, physicochemical variation, residue mobility, and thermodynamic stability) performed at Invitae indicates that this missense variant is expected to disrupt ACSF3 protein function.
- For these reasons, this variant has been classified as Pathogenic.

CFTR, Exon 11, c.1521_1523del (p.Phe508del), heterozygous, PATHOGENIC

- This variant, c.1521_1523del, results in the deletion of 1 amino acid(s) of the CFTR protein (p.Phe508del), but otherwise preserves the integrity of the reading frame.
- This variant is present in population databases (rs199826652, gnomAD 1.2%), including at least one homozygous and/or hemizygous individual.
- This variant has been observed in individual(s) with cystic fibrosis and is the most common cause of the condition (PMID: 2475911, 15371902, 23974870). It has also been observed to segregate with disease in related individuals.
- This variant is also known as Δ F508.
- ClinVar contains an entry for this variant (Variation ID: 7105).
- Algorithms developed to predict the effect of variants on protein structure and function are not available or were not evaluated for this variant.
- Experimental studies have shown that this variant affects CFTR function (PMID: 2475911, 23974870).
- For these reasons, this variant has been classified as Pathogenic.

FBP1, Deletion (Exon 1), heterozygous, PATHOGENIC

DOB:

B:

Invitae #: RQ5318945

- This variant is a gross deletion of the genomic region encompassing exon(s) 1 of the FBP1 gene, which includes the initiator codon. This deletion extends beyond the assayed region for this gene and therefore may encompass additional genes. It is expected to result in an absent or disrupted protein product. Loss-of-function variants in FBP1 are known to be pathogenic (PMID: 9382095, 19259699, 27101822).
- A similar copy number variant has been observed in individual(s) with fructose-1,6-bisphosphatase deficiency (PMID: 11286391).
- For these reasons, this variant has been classified as Pathogenic.

POMT1, Exon 7, c.579_580del (p.Val195Argfs*42), heterozygous, PATHOGENIC

- This sequence change creates a premature translational stop signal (p.Val195Argfs*42) in the POMT1 gene. It is expected to result in an absent or disrupted protein product. Loss-of-function variants in POMT1 are known to be pathogenic (PMID: 12369018, 15637732, 16575835).
- This variant is not present in population databases (gnomAD no frequency).
- This variant has not been reported in the literature in individuals affected with POMT1-related conditions.
- ClinVar contains an entry for this variant (Variation ID: 817606).
- For these reasons, this variant has been classified as Pathogenic.

TYR, Exon 1, c.325G>A (p.Gly109Arg), heterozygous, PATHOGENIC

- This sequence change replaces glycine, which is neutral and non-polar, with arginine, which is basic and polar, at codon 109 of the TYR protein (p.Gly109Arg).
- This variant is present in population databases (rs61753253, gnomAD 0.01%).
- This missense change has been observed in individual(s) with oculocutaneous albinism (PMID: 11295837, 27734839, 29345414; Invitae). In at least one individual the data is consistent with being in trans (on the opposite chromosome) from a pathogenic variant.
- ClinVar contains an entry for this variant (Variation ID: 99562).
- Advanced modeling of protein sequence and biophysical properties (such as structural, functional, and spatial information, amino acid conservation, physicochemical variation, residue mobility, and thermodynamic stability) performed at Invitae indicates that this missense variant is expected to disrupt TYR protein function.
- For these reasons, this variant has been classified as Pathogenic.

Residual risk

No carrier test can detect 100% of carriers. There still remains a small risk of being a carrier after a negative test (residual risk). Residual risk values assume a negative family history and are inferred from published carrier frequencies and estimated detection rates based on testing technologies used at Invitae. You can view Invitae's complete Carrier detection rates and residual risks document (containing all carrier genes) online at https://www.invitae.com/carrier-residual-risks/. Additionally, the order-specific information for this report is available to download in the portal (under this order's documents) or can be requested by contacting Invitae Client Services. The complete Carrier detection rates and residual risks document will not be applicable for any genes with specimen-specific limitations in sequencing and/or deletion/duplication coverage. Please see the final bullet point in the Limitations section of this report to view if this specimen had any gene-specific coverage gaps.

DOR-

Invitae #: RQ5318945

Methods

■ Genomic DNA obtained from the submitted sample is enriched for targeted regions using a hybridization-based protocol, and sequenced using Illumina technology. Unless otherwise indicated, all targeted regions are sequenced with ≥50x depth or are supplemented with additional analysis. Reads are aligned to a reference sequence (GRCh37), and sequence changes are identified and interpreted in the context of a single clinically relevant transcript, indicated in the Genes Analyzed table. Enrichment and analysis focus on the coding sequence of the indicated transcripts, 20bp of flanking intronic sequence, and other specific genomic regions demonstrated to be causative of disease at the time of assay design. Promoters, untranslated regions, and other non-coding regions are not otherwise interrogated. Exonic deletions and duplications are called using an in-house algorithm that determines copy number at each target by comparing the read depth for each target in the proband sequence with both mean read-depth and read-depth distribution, obtained from a set of clinical samples. Markers across the X and Y chromosomes are analyzed for quality control purposes and may detect deviations from the expected sex chromosome complement. Such deviations may be included in the report in accordance with internal guidelines. Invitae utilizes a classification methodology to identify next-generation sequencing (NGS)-detected variants that require orthogonal confirmation (Lincoln, et al. J Mol Diagn. 2019 Mar;21(2):318-329). Confirmation of the presence and location of reportable variants is performed as needed based on stringent criteria using one of several validated orthogonal approaches (PubMed ID 30610921). Sequencing is performed by Invitae Corporation (1400 16th Street, San Francisco, CA 94103, #05D2040778).

The following additional analyses are performed if relevant to the requisition. For GBA the reference genome has been modified to mask the sites of polymorphic paralog sequence variants (PSVs) in both the gene and pseudogene. For CYP21A2 and GBA, if one or more reportable variants, gene conversion, or fusion event is identified via our NGS pipeline (see Limitations), these variants are confirmed by PacBio sequencing of an amplicon generated by long-range PCR and subsequent short-range PCR. In some cases, it may not be possible to disambiguate between the gene and pseudogene. For GJB2, the reportable range includes large upstream deletions overlapping GJB6. For HBA1/2, the reference genome has been modified to force some sequencing reads derived from HBA1 to align to HBA2, and variant calling algorithms are modified to support an expectation of 4 alleles in these regions. HBA1/2 copy number calling is performed by a custom hypothesis testing algorithm which generates diplotype calls. If sequence data for a sample does not support a unique high confidence match from among hypotheses tested, that sample is flagged for manual review. Copy number variation is only reported for coding sequence of HBA1 and HBA2 and the HS-40 region. This assay does not distinguish among the -α3.7 subtypes, and all -α3.7 variants are called as HBA1 deletions. This assay may not detect overlapping copy gain and copy loss events when the breakpoints of those events are similar. For FMR1, cytosine-guanine-guanine (CGG) triplet repeats in the 5' untranslated region (5' UTR) of the FMR1 gene are detected by triplet repeat-primed PCR (RP-PCR) with fluorescently labeled primers followed by capillary electrophoresis. Reference ranges: Normal: <45 CGG repeats, intermediate: 45-54 CGG repeats, premutation: 55-200 CGG repeats, full mutation: >200 CGG repeats. For alleles with 55-90 triplet repeats, the region surrounding the FMR1 repeat is amplified by PCR. The PCR amplicons are then processed through PacBio SMRTBell library prep and sequenced using PacBio long read technology. The number of AGG interruptions within the 55-90 triplet repeat is read directly from the resulting DNA sequences.

- This report only includes variants that have a clinically significant association with the conditions tested as of the report date. Variants of uncertain significance, benign variants, and likely benign variants are not included in this report. However, if additional evidence becomes available to indicate that the clinical significance of a variant has changed, Invitae may update this report and provide notification.
- A PMID is a unique identifier referring to a published, scientific paper. Search by PMID at http://www.ncbi.nlm.nih.gov/pubmed.
- An rsID is a unique identifier referring to a single genomic position, and is used to associate population frequency information with sequence changes at that position. Reported population frequencies are derived from a number of public sites that aggregate data from large-scale population sequencing projects, including ExAC (http://exac.broadinstitute.org), gnomAD (http://gnomad.broadinstitute.org), and dbSNP (http://ncbi.nlm.nih.gov/SNP).

Disclaimer

DNA studies do not constitute a definitive test for the selected condition(s) in all individuals. It should be realized that there are possible sources of error. Errors can result from trace contamination, rare technical errors, rare genetic variants that interfere with analysis, recent scientific developments, and alternative classification systems. This test should be one of many aspects used by the healthcare provider to help with a diagnosis and treatment plan, but it is not a diagnosis itself. This test was developed and its performance characteristics determined by Invitae. It has not been cleared or approved by

DOB:

Invitae #: RQ5318945

the FDA. The laboratory is regulated under the Clinical Laboratory Improvement Act (CLIA) as qualified to perform high-complexity clinical tests (CLIA ID: 05D2040778). This test is used for clinical purposes. It should not be regarded as investigational or for research.

Limitations

- Based on validation study results, this assay achieves >99% analytical sensitivity and specificity for single nucleotide variants, insertions and deletions <15bp in length, and exon-level deletions and duplications. Invitae's methods also detect insertions and deletions larger than 15bp but smaller than a full exon but sensitivity for these may be marginally reduced. Invitae's deletion/duplication analysis determines copy number at a single exon resolution at virtually all targeted exons. However, in rare situations, single-exon copy number events may not be analyzed due to inherent sequence properties or isolated reduction in data quality. Certain types of variants, such as structural rearrangements (e.g. inversions, gene conversion events, translocations, etc.) or variants embedded in sequence with complex architecture (e.g. short tandem repeats or segmental duplications), may not be detected. Additionally, it may not be possible to fully resolve certain details about variants, such as mosaicism, phasing, or mapping ambiguity. Unless explicitly guaranteed, sequence changes in the promoter, non-coding exons, and other non-coding regions are not covered by this assay. Please consult the test definition on our website for details regarding regions or types of variants that are covered or excluded for this test. This report reflects the analysis of an extracted genomic DNA sample. While this test is intended to reflect the analysis of extracted genomic DNA from a referred patient, in very rare cases the analyzed DNA may not represent that individual's constitutional genome, such as in the case of a circulating hematolymphoid neoplasm, bone marrow transplant, blood transfusion, chimerism, culture artifact or maternal cell contamination.
- PTPRC: Sequencing analysis is not offered for exons 3, 15. ABCC2: Deletion/duplication analysis is not offered for exons 24-25. OTOA: Deletion/ duplication and sequencing analysis is not offered for exons 20-28. DUOX2: Deletion/duplication and sequencing analysis is not offered for exons 6-7. TBCE: Sequencing analysis for exons 2 includes only cds +/- 10 bp. GNE: Sequencing analysis for exons 8 includes only cds +/- 10 bp. NEB: Deletion/duplication analysis is not offered for exons 82-105. NEB variants in this region with no evidence towards pathogenicity are not included in this report, but are available upon request. PKHD1: Deletion/duplication analysis is not offered for exon 13. GALE: Sequencing analysis for exons 10 includes only cds +/- 5 bp. DDX11: NM_030653.3:c.1763-1G>C variant only. SMN1: Systematic exon numbering is used for all genes, including SMN1, and for this reason the exon typically referred to as exon 7 in the literature (PMID: 8838816) is referred to as exon 8 in this report. This assay unambiguously detects SMN1 exon 8 copy number. The presence of the g.27134T>G variant (also known as c.*3+80T>G) is reported if SMN1 copy number = 2. SMN1 or SMN2: NM_000344.3:c.*3+80T>G variant only. VPS13A: Deletion/duplication analysis is not offered for exons 2-3, 27-28. BBS9: Deletion/duplication analysis is not offered for exon 4. WRN: Deletion/duplication analysis is not offered for exons 10-11. Sequencing analysis for exons 8, 10-11 includes only cds +/- 10 bp. CFTR: Sequencing analysis for exons 7 includes only cds +/- 10 bp. EYS: Sequencing analysis for exons 30 includes only cds +/- 0 bp. FH: Sequencing analysis for exons 9 includes only cds +/- 10 bp. GHR: Deletion/ duplication and sequencing analysis is not offered for exon 3. OAT: Deletion/duplication analysis is not offered for exon 2. ANO10: Sequencing analysis for exons 8 includes only cds +/- 0 bp. ATP8B1: Sequencing analysis for exons 19 includes only cds +/- 10 bp. FANCD2: Deletion/ duplication analysis is not offered for exons 14-17, 22 and sequencing analysis is not offered for exons 15-17. Sequencing analysis for exons 6, 14, 18, 20, 23, 25, 34 includes only cds +/- 10 bp. TSFM: Sequencing analysis is not offered for exon 5. VPS53: Sequencing analysis for exons 14 includes only cds +/- 5 bp. COL11A2: Deletion/duplication analysis is not offered for exon 36. HBA1/2: This assay is designed to detect deletions and duplications of HBA1 and/or HBA2, resulting from the -alpha20.5, --MED, --SEA, --FIL/--THAI, -alpha3.7, -alpha4.2, anti3.7 and anti4.2. Sensitivity to detect other copy number variants may be reduced. Detection of overlapping deletion and duplication events will be limited to combinations of events with significantly differing boundaries. In addition, deletion of the enhancer element HS-40 and the sequence variant, Constant Spring (NM_000517.4:c.427T>C), can be identified by this assay. MTHFR: The NM_005957.4:c.665C>T (p.Ala222Val) (aka 677C>T) and c.1286A>C (p.Glu429Ala) (aka 1298A>C) variants are not reported in our primary report. GBA: c.84dupG (p.Leu29Alafs*18), c.115+1G>A (Splice donor), c.222_224delTAC (p.Thr75del), c.475C>T (p.Arg159Trp), c.595_596delCT (p.Leu199Aspfs*62), c.680A>G (p.Asn227Ser), c.721G>A (p.Gly241Arg), c.754T>A (p.Phe252lle), c.1226A>G (p.Asn409Ser), c.1246G>A (p.Gly416Ser), c.1263_1317del (p.Leu422Profs*4), c.1297G>T (p.Val433Leu), c.1342G>C (p.Asp448His), c.1343A>T (p.Asp448Val), c.1448T>C (p.Leu483Pro), c.1504C>T (p.Arg502Cys), c.1505G>A (p.Arg502His), c.1603C>T (p.Arg535Cys), c.1604G>A (p.Arg535His) variants only. Rarely, sensitivity to detect these variants may be reduced. When sensitivity is reduced, zygosity may be reported as "unknown". CYP21A2: Analysis includes the most common variants (c.92C>T(p.Pro31Leu), c.293-13C>G (intronic), c.332_339delGAGACTAC (p.Gly111Valfs*21), c.518T>A (p.Ile173Asn), c.710T>A (p.Ile237Asn), c.713T>A (p.Val238Glu), c.719T>A (p.Met240Lys), c.844G>T (p.Val282Leu), c.923dupT (p.Leu308Phefs*6), c.955C>T (p.Gln319*), c.1069C>T(p.Arg357Trp), c.1360C>T (p.Pro454Ser) and the 30Kb deletion) as well as select rare HGMD variants only (list available upon request). Full gene duplications are reported only in the presence of a pathogenic variant(s). When a duplication and a pathogenic variant(s) is identified, phase (cis/trans) cannot be determined. Full gene deletion analysis is not offered. Sensitivity to detect these variants, if they result from complex gene conversion/fusion events, may be reduced. AIPL1: Sequencing analysis for exons 2 includes only cds +/- 10 bp. LIFR: Sequencing analysis for

DOB:

Patient name: DONOR 13016

Invitae #: RQ5318945

exons 3 includes only cds +/- 5 bp. AMN: Deletion/duplication analysis is not offered for exon 1. TYR: Deletion/duplication and sequencing analysis is not offered for exon 5. TG: Deletion/duplication analysis is not offered for exon 18. Sequencing analysis for exons 44 includes only cds +/- 0 bp. FANCL: Sequencing analysis for exons 4, 10 includes only cds +/- 10 bp. PEX1: Sequencing analysis for exons 16 includes only cds +/- 0 bp. USH1C: Deletion/duplication analysis is not offered for exons 5-6. ATM: Sequencing analysis for exons 6, 24, 43 includes only cds +/- 10 bp. FAH: Deletion/duplication analysis is not offered for exon 14. GALC: Deletion/duplication analysis is not offered for exon 6. MLC1: Sequencing analysis for exons 11 includes only cds +/- 10 bp.

This table is relevant to patient report RQ5318945 Issue date: 07/31/2023

This table displays residual risks after a negative result for each of the genes and corresponding disorders. The values provided assume a negative family history and the absence of symptoms for each disorder. For genes associated with both dominant and recessive inheritance, the numbers in this table apply to the recessive condition(s) associated with the gene, unless otherwise noted. Residual risk values are provided for disorders when carrier frequency is greater than 1 in 500. For disorders with carrier frequency equal to, or less than, 1 in 500, residual risk is considered to be reduced substantially. When provided, residual risk values are inferred from published carrier frequencies, and estimated detection rates are based on testing technologies used at Invitae. Residual risks are provided only as a guide for assessing approximate risk given a negative result; values may vary based on the ethnic background(s) of an individual. For any genes marked with an asterisk*, refer to the Limitations section of the patient report for detailed coverage information. In the case of a sample-specific limitation, "N/A" indicates that a residual risk value could not be calculated. AR = autosomal recessive, XL = X-linked, AD = autosomal dominant.

| DISORDER (INHERITANCE) | GENE | ETHNICITY | CARRIER FREQUENCY | DETECTION RATE | RISK TO BE A CARRIER AFTER NEGATIVE RESULT |

Cytogenetic Report

CHROMOSOME ANALYSIS, BLOOD - 14596

CHROMOSOME ANALYSIS, BLOOD

Order ID: 23-306061 Specimen Type: Blood

Clinical Indication: GAMETE DONOR

RESULT:

NORMAL MALE KARYOTYPE

INTERPRETATION:

Chromosome analysis revealed normal G-band patterns within the limits of standard cytogenetic analysis.

Please expect the results of any other concurrent study in a separate report.

NOMENCLATURE:

46,XY

ASSAY INFORMATION:

Method: G-Band (Digital Analysis: MetaSyst

Cells Counted:20Band Level:450Cells Analyzed:5Cells Karyotyped:5

This test does not address genetic disorders that cannot be detected by standard cytogenetic methods or rare events such as low level mosaicism or subtle rearrangements. A portion of the testing was performed at sjc2.
